**ABSTRACT :** Consistency of combining ability over  $F_4$  and  $F_5$  generations derived hybrids, locations, seasons and testers was estimated in current study. Heterotic box was created by crossing DSMR 10 line (stay-green group) with DSG 3-5 line (robust group) and DRGR 32-100 line with DRGR 24-178 line (RGR group) to generate two highly diverse base populations. The resulted  $F_1$ s were advanced to  $F_4$  generation for evaluating the recombinational variability which were generated. Selected  $F_4$  lines of (DSMR10 x DSG 3-5) cross were crossed with DRGR 32-100 ( $T_1$ ) and DRGR 24-178 ( $T_2$ ), DH 7225 ( $T_3$ ) and DRGR 4 ( $T_4$ ). Lines of (DRGR 32-100 x DRGR 24-178) cross were crossed with DSMR 10 ( $T_5$ ) and DSG 3-5 ( $T_6$ ), DH 7225 ( $T_7$ ) and DR 8 ( $T_8$ ). Heritability of combining ability was 26 per cent for lines of (DSMR10 x DSG 3-5) cross and 45.50 per cent for lines of (DRGR 24-178 x DRGR 32-100) cross. Correlation for  $F_1$ s of RSG group and RGR group was ( $r=0.59^{**}$ ) and ( $r=0.80^{**}$ ), respectively, which was highly significant for both groups. The  $F_4$  derived hybrids of RSG group and RGR group evaluated at two locations showed the correlation value ( $r=-0.077$ ) and ( $r=0.237$ ), respectively. DH 7225 ( $T_3$ ) have shown gca effect ( $309.99^{**}$ ) in population I RSG  $F_4$  lines and ( $372.38^{**}$ ) in population I RSG  $F_5$  lines. In population II RGR  $F_4$  lines and population II RGR  $F_5$  lines, DR 8 ( $T_8$ ) have shown gca effect ( $285.36^{**}$ ) and ( $336.46^{**}$ ). DH 7225 ( $T_3$ ) in RSG population and DR 8 ( $T_8$ ) in RGR population have shown the consistency of combining ability over tester.

**Key Words :** Combining ability, cotton, heterotic box, reciprocal selection

Cotton is an important often cross pollinated crop where heterosis is successfully exploited through release of both inter and intra specific hybrids. The ease of manual emasculating and crossing has been the reason for enabling manual hybrid seed production and this also enables intermating simulating random mating where by the procedures of population improvement schemes defined for cross pollinated crops can also be applied to improve hybrid performance. Though heterotic groups are formed and exploited in maize there are limited attempts made to develop heterotic groups based on performance of hybrids and

exploit them through population improvement schemes in self pollinated crops. Earlier studies were conducted at University of Agricultural Sciences at Dharwad such as Pranesh (2014) and Kenchareddi (2014) on heterotic groups in cotton. Patil *et al.*, (2011), Pranesh (2014) and Kencharaddi (2014) demonstrated the possibility of identifying a heterotic box and improving combining ability through modified (suited the mating system of cotton) reciprocal selection for combining ability in  $F_4$  generation.

Many quantitative traits are measured in the  $F_1$ , seed cotton yield of the  $F_1$  can be adjudged as the best yardstick to measure

combining ability (ability to combine with the tester) of the parental line. Based on performance (seed cotton yield) of hybrids, and the groups of parents which were diverse leading to high heterosis and productivity, the hybrids have been identified and constituents of each heterotic group were identified and revised over years based on consistency of observations. The lines of robust/stay green in general gave productive hybrids (heterotic) when crossed with the RGR group. Some of the diverse heterotic groups developed over years include robust *v/s* compact types, robust/stay green *v/s* compact types, robust/stay green *v/s* high relative growth rate (RGR) groups (Patil, 2010).

Exploitation of heterotic groups was taken up through selection in segregating generations of opposite groups Pranesh (2014) and Kencharaddi (2014). The material used for present study was derived from the diverse pairs of two parents (heterotic box) involving robust/stay green (RSG) versus high relative growth rate (RGR) heterotic groups. This heterotic box was chosen based on predicted performance of double cross hybrid (Kencharaddi *et al.*, 2015) for initiating reciprocal selection for combining ability.

## MATERIALS AND METHODS

**Material used :** Initially the material was created for exploiting opposite heterotic groups by identification of heterotic box involving elite combiner lines of opposite heterotic groups. Because of this reason elite combiners DSMR10 line (of stay green group), DSG 3-5 line (of robust group) and two DRGR 32-100 and DRGR 24-178 lines (of RGR group) were chosen to develop a

heterotic box.

These four elite lines were crossed in below given pattern to generate two highly diverse base populations.

Then the F<sub>1</sub>s of within group crosses were advanced to F<sub>4</sub> generation and recombinational variability was evaluated in the same. The F<sub>4</sub> lines are selected for evaluation of combining ability because in many studies it is seen that F<sub>4</sub> lines have greater uniformity as compared to the corresponding F<sub>3</sub> lines.

In the current study, to check consistency of combining ability over generation ten randomly selected F<sub>4</sub> lines from both the populations were evaluated for combining ability. The same lines of both the populations were advanced to the F<sub>5</sub> generation and again evaluated for the consistency of combining ability. In the heterotic box utilized in present study F<sub>4</sub> lines of both populations were evaluated for combining ability by Kencharaddi, 2014 at another location (Belavatgi in Karnataka) during 2013. Since study on the combining ability of the same ten lines was repeated during 2014-2015 in Dharwad (Karnataka) it was possible to understand how far assessment of combining ability reveals consistency of combining ability across seasons and locations.

**Testers :** These selected F<sub>4</sub> lines were crossed with the parents of the opposite group population *i.e.* lines of (DSMR 10 × DSG 3-5) cross

were crossed with DRGR 32-100 and DRGR 24-178 (opposite testers) and lines of (DRGR 32-100 × DRGR 24-178) cross were crossed with DSMR 10 and DSG 3-5 (opposite testers). The selected lines were also crossed with one additional tester DH 7225 which was common for both populations and one diverse tester.  $F_4$  lines of (DSMR 10 × DSG 3-5) population were crossed to additional diverse tester DRGR 4 and DR 8 was used as additional diverse tester for  $F_4$  lines of (DRGR 32-100 × DRGR 24-178) population. Hence, it was possible to assess consistency of combining ability over testers. This scheme of assessing combining ability was repeated in  $F_5$  generation by advancing selected  $F_4$  lines to  $F_5$  generation. Performance of derived  $F_1$ s was utilized as the index of combining ability. Three approaches were used for checking consistency of combining ability over generations.

**I. Regression Approach :** The seed cotton yield values of derived  $F_1$ s involving lines in two successive generations (based on  $F_4$  and  $F_5$  lines) were utilized for determining regression values *i.e.*,  $b_{F_5F_4}$ . Heritability of combining ability was calculated based on regression approach.

$$h^2 = (b / 2r_{XY})$$

where;

$h^2$  = Narrow sense heritability

$b$  = Regression coefficient

$r_{XY}$  = Coefficient of parentage

**II. Correlation of derived  $F_1$ s performance:**

Simple correlation of  $F_4$  derived hybrids with  $F_5$  derived hybrids was also calculated to know the consistency of combining ability.

**III. Grouping performance of derived  $F_1$ s:**

The  $F_4$  and  $F_5$  derived hybrids were ranked

based on performance (seed cotton yield) and compared for consistency of combining ability over generations.

## RESULTS AND DISCUSSION

Two opposite segregating  $F_4$  populations representing a heterotic box of cotton were utilized for assessing combining ability by using four testers. Ten lines of each  $F_4$  population were evaluated again in  $F_5$  generation to check consistency of combining ability.

Consistency of combining ability was calculated over  $F_4$  and  $F_5$  generations, locations, seasons and testers based on the performance of derived hybrids. The performance of derived hybrids was taken as the measure of combining ability because of the fact that line with higher combining ability will combine well with taster and it will be revealed in the form of superior performance. The results are described under following headings:-

### Consistency of combining ability over generations

#### 1. Heritability of combining ability :

Combining ability is an important aspect in development of hybrids, so it is necessary to know about the combining ability of parents and hybrids. For the same objective the  $F_4$  lines are crossed with the four selected testers and their derived  $F_1$ s were generated. The same selected  $F_4$  lines were advanced to  $F_5$  generation and again crossed with the previously used testers and derived  $F_1$ s are generated. These derived  $F_1$ s of both the generation ( $F_4$  and  $F_5$  derived hybrids) are evaluated for calculating the

Regression of performance of derived F<sub>1</sub> (combining ability) involving lines in F<sub>5</sub> and F<sub>4</sub> generations ( $b_{F_5 \text{ on } F_4}^2$ ) = 0.85  
 Heritability ( $h_{NS}^2$ ) for Combining Ability = 45.50 per cent  
 Correlation of F<sub>4</sub> and F<sub>5</sub> derived hybrids (r) = 0.80\*\*

heritability of combining ability.

Based on the regression of  $F_5$  derived hybrids over the  $F_4$  derived hybrids of the same lines of (DSMR10  $\times$  DSG 3-5) cross and (DRGR 24-178  $\times$  DRGR 32-100), the heritability of the combining ability was calculated. According to the formulae regression value was divided with the coefficient of parentage ( $2r_{xy} = 15/16$ ) depending upon the generations of the lines used in the analysis. Regression value (b) for the lines of (DSMR 10  $\times$  DSG 3-5) cross was (0.49). This regression value has been divided with the coefficient of parentage ( $2r_{xy} = 15/16$ ) to obtain the heritability of combining ability which was 26 per cent (Table 1) for the lines of (DSMR 10  $\times$  DSG 3-5) cross. Regression value (b) for the lines of (DRGR 24-178  $\times$  DRGR 32-100) cross was (0.85) and heritability of combining ability was 45.50 per cent (Table 2).

**2. Correlation :** The correlation of  $F_4$  and  $F_5$  derived hybrids was calculated to check the consistency of the combining ability. The mean seed cotton yield of the derived hybrids was used in correlation analysis. For the derived hybrids of RSG group the correlation obtained was ( $r = 0.59^{**}$ ) (Table 1). The correlation was found to be highly significant showing that derived hybrids were related to each other and their performance was consistent over generations. This shows that the lines of RSG group have consistency in combining ability over generations. In case of RGR group correlation obtained for the derived hybrids was ( $r = 0.80^{**}$ ) (Table 2). In RGR group also correlation of derived hybrids was found highly significant. This result shows that the lines have consistency in combining ability over generations.

**3. Rankings of derived hybrids :** The forty derived hybrids are divided into various groups based on their ranking of mean seed cotton yield among them. The  $F_4$  derived hybrids were ranked among them and similarly  $F_5$  derived hybrids were also ranked. Then overall mean of seed cotton yield of  $F_4$  and  $F_5$  derived hybrids were taken. Finally the overall mean rank of derived hybrids was compared with the  $F_4$  rank and  $F_5$  rank. The rankings were given in the table 1 and 2 for RSG and RGR groups respectively. In the derived hybrids of RSG group the hybrids coming under the top eight club were having the same ranks (difference in ranks were more or less similar) in both generations (Table 1). The hybrids coming under the bottom eight club also revealed the same pattern of ranks. Regarding the derived hybrids of RGR group similar trends were observed (Table 2). The result shows that derived hybrids of both groups had consistency in their performance over generations. Hence it can be concluded from results that RSG and RGR lines showed consistency in combining ability over generations.

**Consistency of combining ability over locations and seasons :** The  $F_4$  derived hybrids were evaluated for the consistency of combining ability over locations and seasons, for which the randomly selected  $F_4$  derived hybrids which were already evaluated were taken. These previously evaluated  $F_4$  derived hybrids along with  $F_5$  derived hybrids of same lines were evaluated for this study. This experiment was done in both the group *i.e.* RSG and RGR group.

**1. Correlation :** The correlation between

**Table 3.** Correlation analysis of  $F_4$  derived hybrids of RSG group (DSMR 10 × DSG 3-5) over location and seasons

Correlation (r) = (-0.237)

the  $F_4$  derived hybrids evaluated at the two places Belavatgi (2013) and Dharwad (2015) was calculated. The mean seed cotton yield data of  $F_4$  derived hybrids which was evaluated in another study by Kencharaddi (2014) at the Belavatgi farm was used. This old data were correlated with the mean seed cotton yield data of same  $F_4$  derived hybrids which were re-evaluated at ARS Dharwad, farm. The results of correlation analysis are presented below for RSG and RGR  $F_4$  derived hybrids.

The  $F_4$  derived hybrids of RSG group evaluated at two places has shown the correlation value ( $r = -0.077$ ) (Table 3). The correlation was non-significant for the  $F_4$  derived hybrids of RSG group showing that the hybrid performance was inconsistent over locations. Considering  $F_4$  derived hybrids of RGR group (Table 4) the correlation value was ( $r = 0.237$ ). In this case also correlation was non-significant for the  $F_4$  derived hybrids which depicts hybrid performance was inconsistent over locations. It can be concluded from results that combining ability over locations and seasons was

inconsistent for both RSG and RGR group.

Consistency of combining ability of hybrids tested in  $F_4$  generation over locations/seasons was low may be because in earlier experiment at Belavatgi crop was grown in intensive management situation during 2012-2013. In present experiment done at ARS, Dharwad crop was grown in rainfed situation. Further the season was harsh during 2014-2015 and rainfall was erratic. The two environments where  $F_4$  derived hybrids were evaluated were so contrasting Hybrids performing better in intensive management situation may have done well at Belavatgi while hybrids tolerant to harsh moisture stress situation may have done well at ARS, Dharwad. This may be the main reason for lack of consistency in performance of  $F_4$  derived hybrids.

### 3. Consistency of combining ability

**over testers :** In the population I RSG  $F_4$  lines the common tester DH 7225 ( $T_3$ ) have the highest gca effect (309.99\*\*) and diverse tester DRGR 4 ( $T_4$ ) have second highest gca effect (67.58\*). In the population I RSG  $F_5$  lines the common tester DH 7225 ( $T_3$ ) have the highest gca effect (372.38\*\*) and diverse tester DRGR 4 ( $T_4$ ) have second highest gca effect (-0.53) (Table 5). Hence, it can be concluded that the common tester DH 7225 ( $T_3$ ) and diverse tester DRGR 4 ( $T_4$ ) have shown the consistency of combining ability in RSG population. In the population II RGR  $F_4$  lines diverse tester DR 8 ( $T_8$ ) have the highest gca effect (285.36\*\*) and common tester DH 7225 ( $T_7$ ) have the second highest gca effect (88.11\*\*) (Table 5). In the population II RGR  $F_5$  lines diverse tester DR 8 ( $T_8$ ) have the highest gca effect (336.46\*\*) and common tester DH 7225 ( $T_7$ ) have

**Table 5.** Consistency of combining ability over testers used for population I RSG  $F_4$  and  $F_5$  lines and population II RGR  $F_4$  and  $F_5$  lines

Sl. No.	Tester	gca effect	
		$F_4$ generation	$F_5$ generation
<b>Population I RSG lines</b>			
1.	DRGR 24-178 ( $T_1$ )	10.91	-272.04**
2.	DRGR 32-100 ( $T_2$ )	-388.48**	-99.8**
3.	DH 7225 ( $T_3$ )	309.99**	372.38**
4.	DRGR 4 ( $T_4$ )	67.58*	-0.53
<b>Population II RGR lines</b>			
5.	DSMR 10 ( $T_5$ )	-312.48**	-350.36**
6.	DSG 3-5 ( $T_6$ )	-60.96*	-66.50*
7.	DH 7225 ( $T_7$ )	88.11**	80.40*
8.	DR 8 ( $T_8$ )	285.36**	336.46**

the second highest gca effect (80.40\*\*). Result shows that diverse tester DR 8 ( $T_8$ ) and common tester DH 7225 ( $T_7$ ) have shown the consistency of combining ability in RGR population.
